

Problem Solving Using Python (CSE1012)

Dr. Abdul Kayom, Assistant Professor, SENSE

Agenda / Contents

- 01 Introduction to File Handling
- 02
- 03
- 04
- 05

writelines() Method

```
file = open("File1.txt", "w")  
lines = ["Hello World, ", "Welcome to the world of Python", "Enjoy Learning  
Python"]  
file.writelines(lines)  
file.close()  
print("Data written to file.....")
```

OUTPUT

```
Data written to file.....
```

append() Method

- Once you have stored some data in a file, you can always open that file again to write more data or append data to it
- To append more data to a file, you must open it using 'a' for text file
- And in 'ab' mode for a binary file

append() Method

- Note that if you open a file in 'w' or 'wb' mode and then start writing data into it, then its existing contents would be overwritten
- So, always open the file in 'a' or 'ab' mode to add more data to existing data stored in the file

append() Method

- Appending data is especially essential when creating a log of events or combining a large set of data into one file

append() Method

```
file = open("File1.txt", "a")  
file.write("\n Python is a very simple yet powerful language")  
file.close()  
print("Data appended to file.....")
```

OUTPUT

```
Data appended to file....."
```

read() Method

- The read() method is used to read a string from an already opened file.

`fileobj.read([count])` #syntax of read() method

- Count is optional
- If not present, it will read from beginning to end

readline() Method

- The readline() method is used to read a single line

readline() Method

```
file = open("File3.txt","r")  
print("First line: ",file.readline())  
print("Second line: ",file.readline())  
File.close()
```

readlines() Method

```
#Read a file using readlines() function  
file = open("File3.txt","r")  
print(file.readlines())  
file.close
```

readlines() Method

```
file = open("File1.txt", "r")  
print(file.read(10))  
file.close()
```

OUTPUT

```
Hello All,
```

Display contents of a file as a list

```
file = open("File3.txt","r")  
print(list(file))  
file.close
```

Loop over the file to display content

#Loop over the file to display contents of the file

```
file = open("File3.txt","r")
```

```
for line in file:
```

```
    print(line)
```

```
file.close()
```

Opening Files using 'with' Keyword

#Opening a file using 'with' Keyword

with open("File3.txt","r") as file:

print(file.read())

Splitting Words

#Splitting Words: prog to split the line into a series of words
with open("File3.txt","r") as file:

```
    line = file.readline()  
    words = line.split()  
    print(words)
```

Other useful File Methods

Method	Description	Example
<code>fileno()</code>	Returns the file number of the file (which is an integer descriptor)	<pre>file = open("File1.txt", "w") print(file.fileno())</pre> OUTPUT 3
<code>flush()</code>	Flushes the write buffer of the file stream	<pre>file = open("File1.txt", "w") file.flush()</pre>
<code>isatty()</code>	Returns True if the file stream is interactive and False otherwise	<pre>file = open("File1.txt", "w") file.write("Hello") print(file.isatty())</pre> OUTPUT False
<code>readline(n)</code>	Reads and returns one line from file. n is optional. If n is specified then atmost n bytes are read	<pre>file = open("Try.py", "r") print(file.readline(10))</pre> OUTPUT file = ope
<code>truncate(n)</code>	Resizes the file to n bytes	<pre>file = open("File.txt", "w") file.write("Welcome to the world of programming...") file.truncate(5) file = open("File.txt", "r") print(file.read())</pre> OUTPUT Welco
<code>rstrip()</code>	Strips off whitespaces including newline characters from the right side of the string read from the file.	<pre>file = open("File.txt") line = file.readline() print(line.rstrip())</pre> OUTPUT Greetings to All !!!

Thank You
